```

void draw() {
  ...
  for (int i = 0 ; i < nodes.length; i++) {
    nodes[i].attract(nodes);
  }
  for (int i = 0 ; i < nodes.length; i++) {
    nodes[i].update();
  }
  fill(0);
  for (int i = 0 ; i < nodes.length; i++) {
    ellipse(nodes[i].x, nodes[i].y, 10, 10);
  }
}

```

- The node array is processed and all other nodes are repelled using the `attract()` function.
- The repelling force has only affected the velocity vectors until now. The positions of the nodes are updated with the `update()` function.
- The node is depicted as a circle.

200 nodes that repel each other.

**SPRINGS AS CONNECTIONS** After repelling nodes, the connections between linked nodes are the second important element of a force-directed layout. Since these connections should attempt to limit themselves to a certain length, the concept of a spring is usually used for this purpose.

[Wikipedia: Force-directed layout](#)

Therefore, the algorithm used to translate this model into practice must enable the connected nodes to move toward one another when they are far apart and to repel each other when they come too close. The following steps are one way to meet these demands. These can then be easily transferred to the corresponding vector functions in the program (in the new class `Spring`).
